

# Introduction

- > A child's language environment plays an important role in their language development, which in turn affects their future success <sup>(1)</sup>
- Use of formal child care has grown, yet little is known about the language environment of these settings <sup>(2, 3)</sup>
- > Of particular concern is a child's ability to understand and learn from speech under noisy conditions <sup>(4)</sup>
- > To date: *no systematic comparisons* of language environments across child care settings exist
- $\succ$  The current study examined the quality of the sound environment of toddlers in homes versus daycares

# Participants

Child Care Settings of toddlers 13–31 months old

- **12 Daycare Centers**
- **7** Home Daycares
- 14 Homes

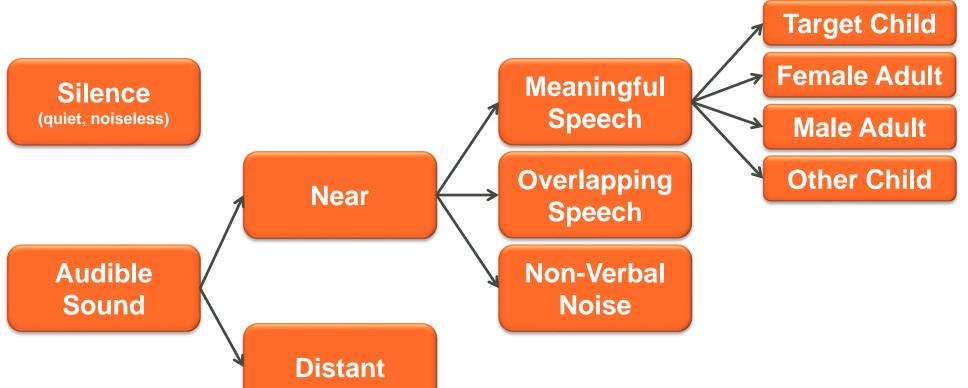

> 2-6 multi-hour recordings per participant

# **Data Collection**

### LENA:

- > Small, lightweight recording device worn by child
- Automated analysis divides recording into segments

 $\succ$  Extracted activity level data using LENA's ADEX tool, creating a table for each recording

Tables contained name, duration, and start time of each segment

### **PRAAT:** (5)

- Wrote script to interface with output from LENA
- Extracted part of wav file based in information in associated table
- Determined intensity and duration of clip/segment
- Averaged intensity (summed duration) of segments over a recording

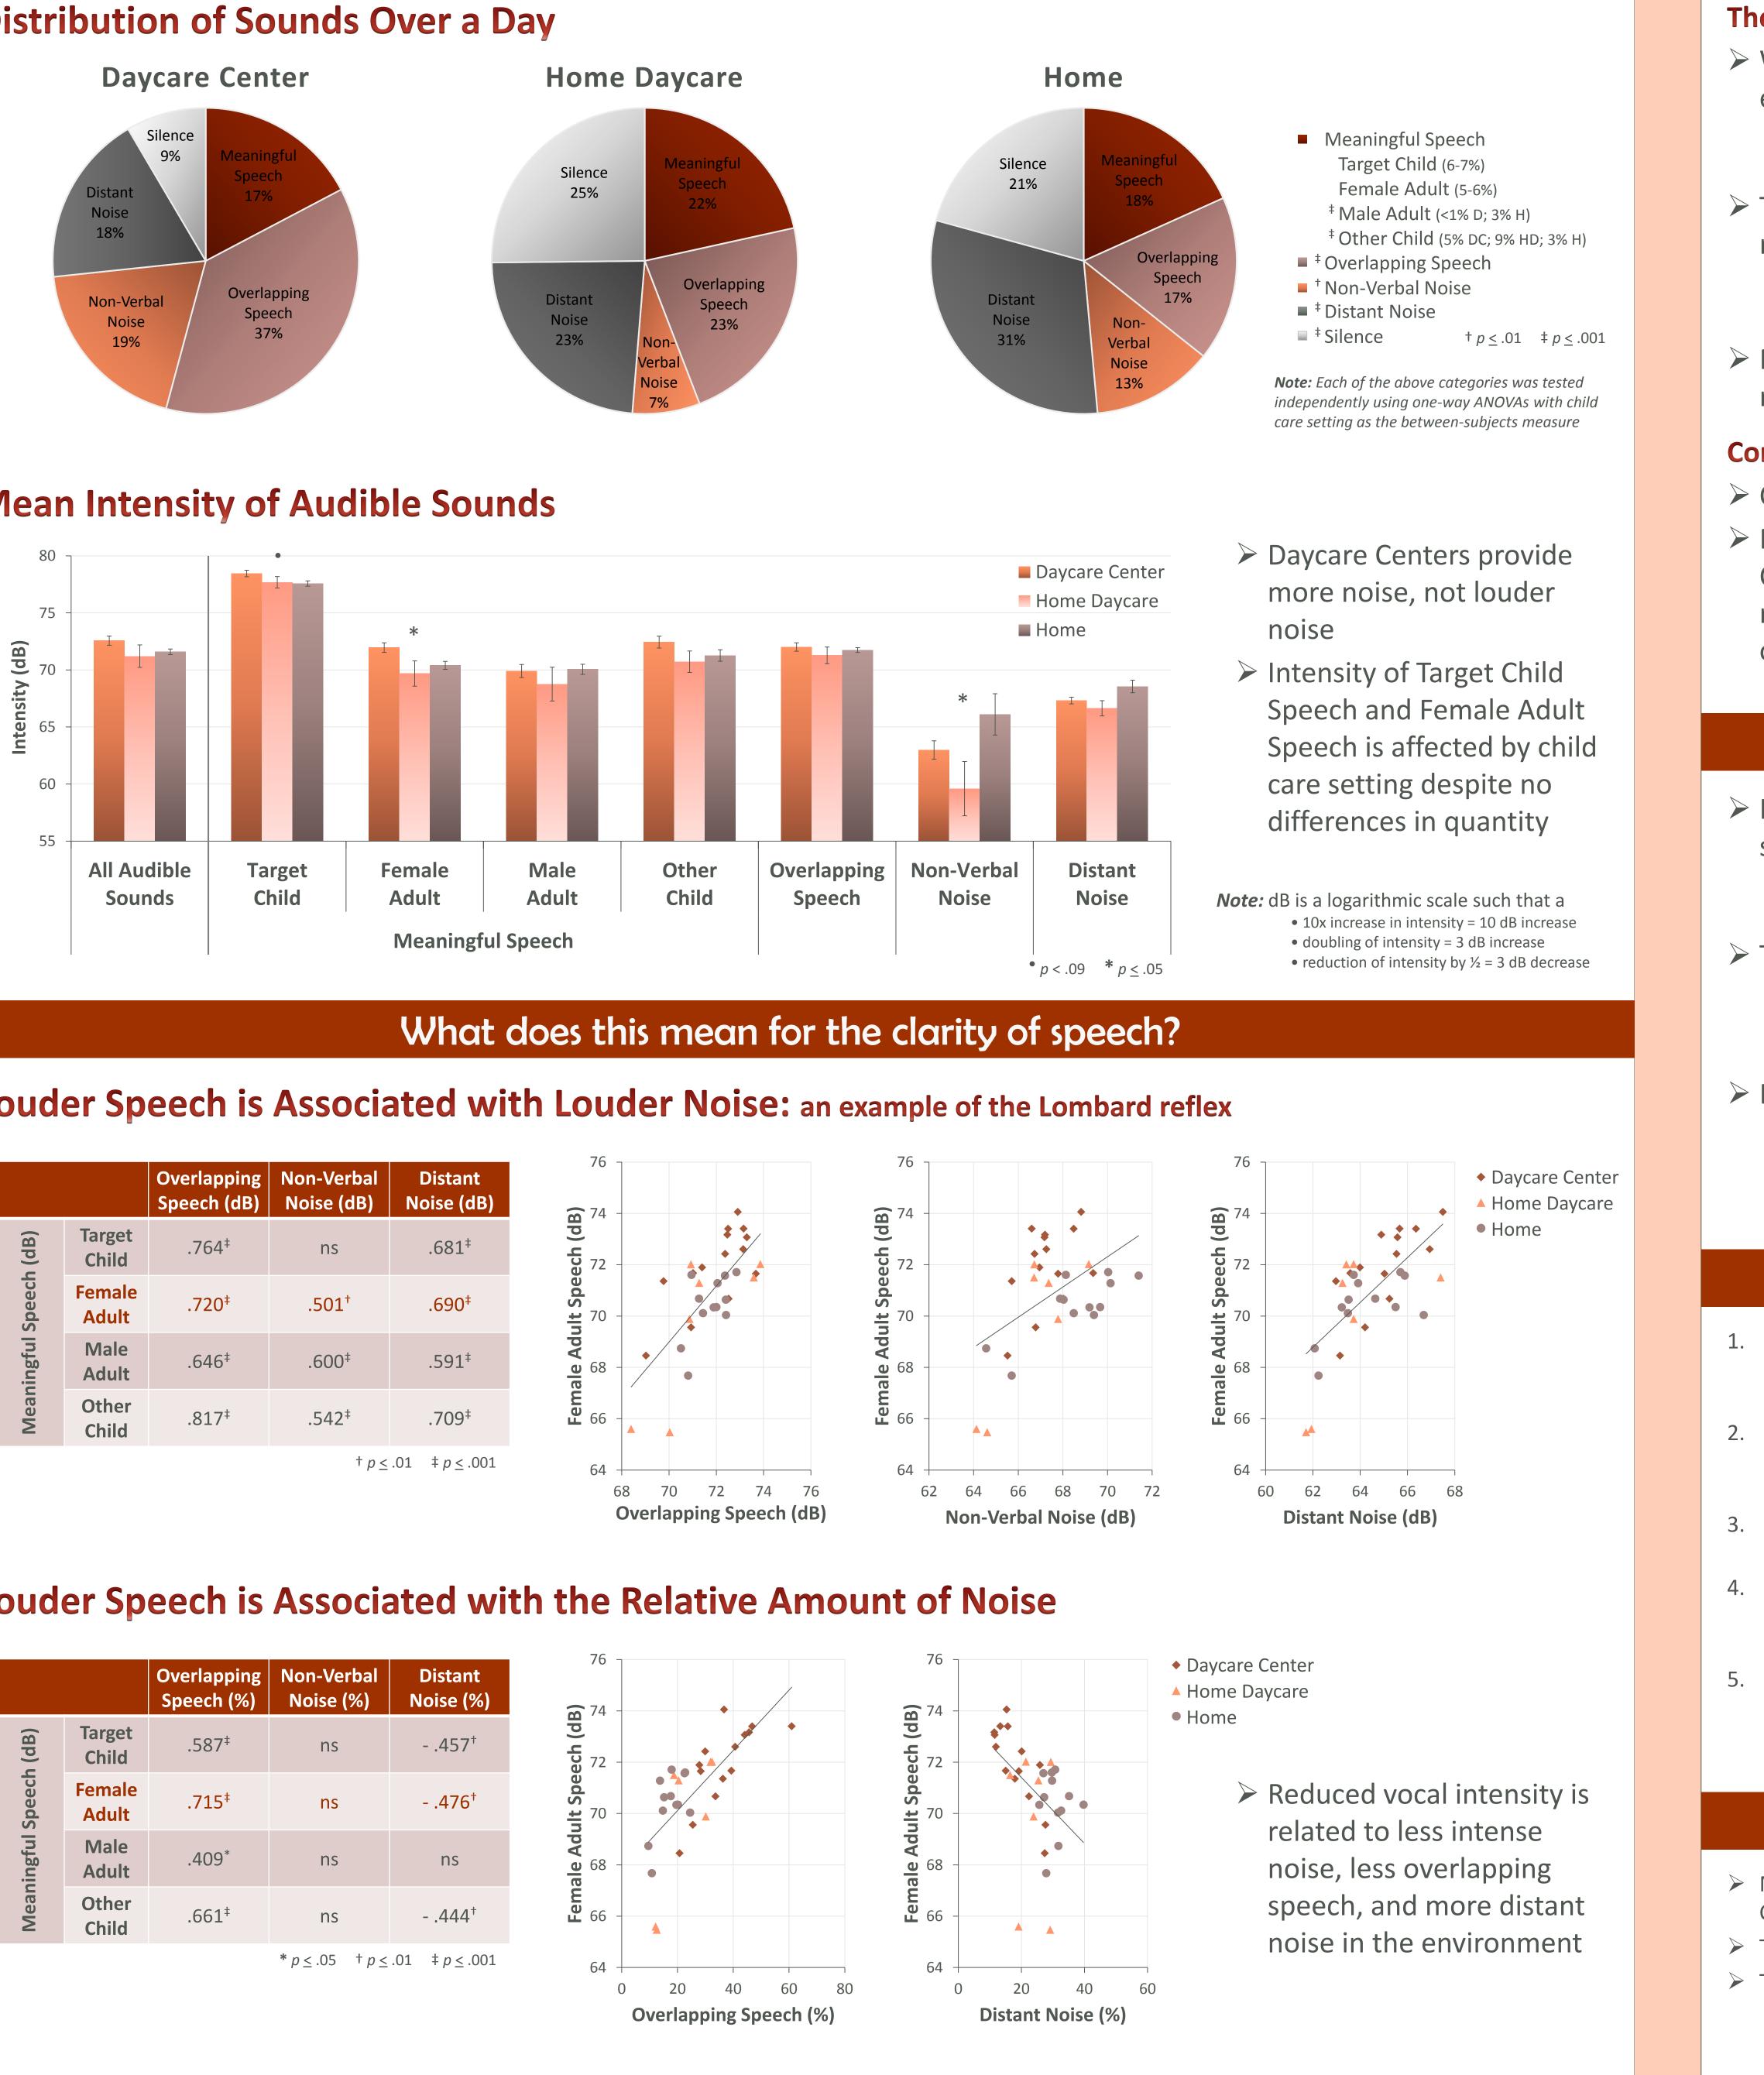

### For each participant

- Averaged intensity of each segment across all recordings
- Summed duration of each segment across all recordings and divided by total recording length

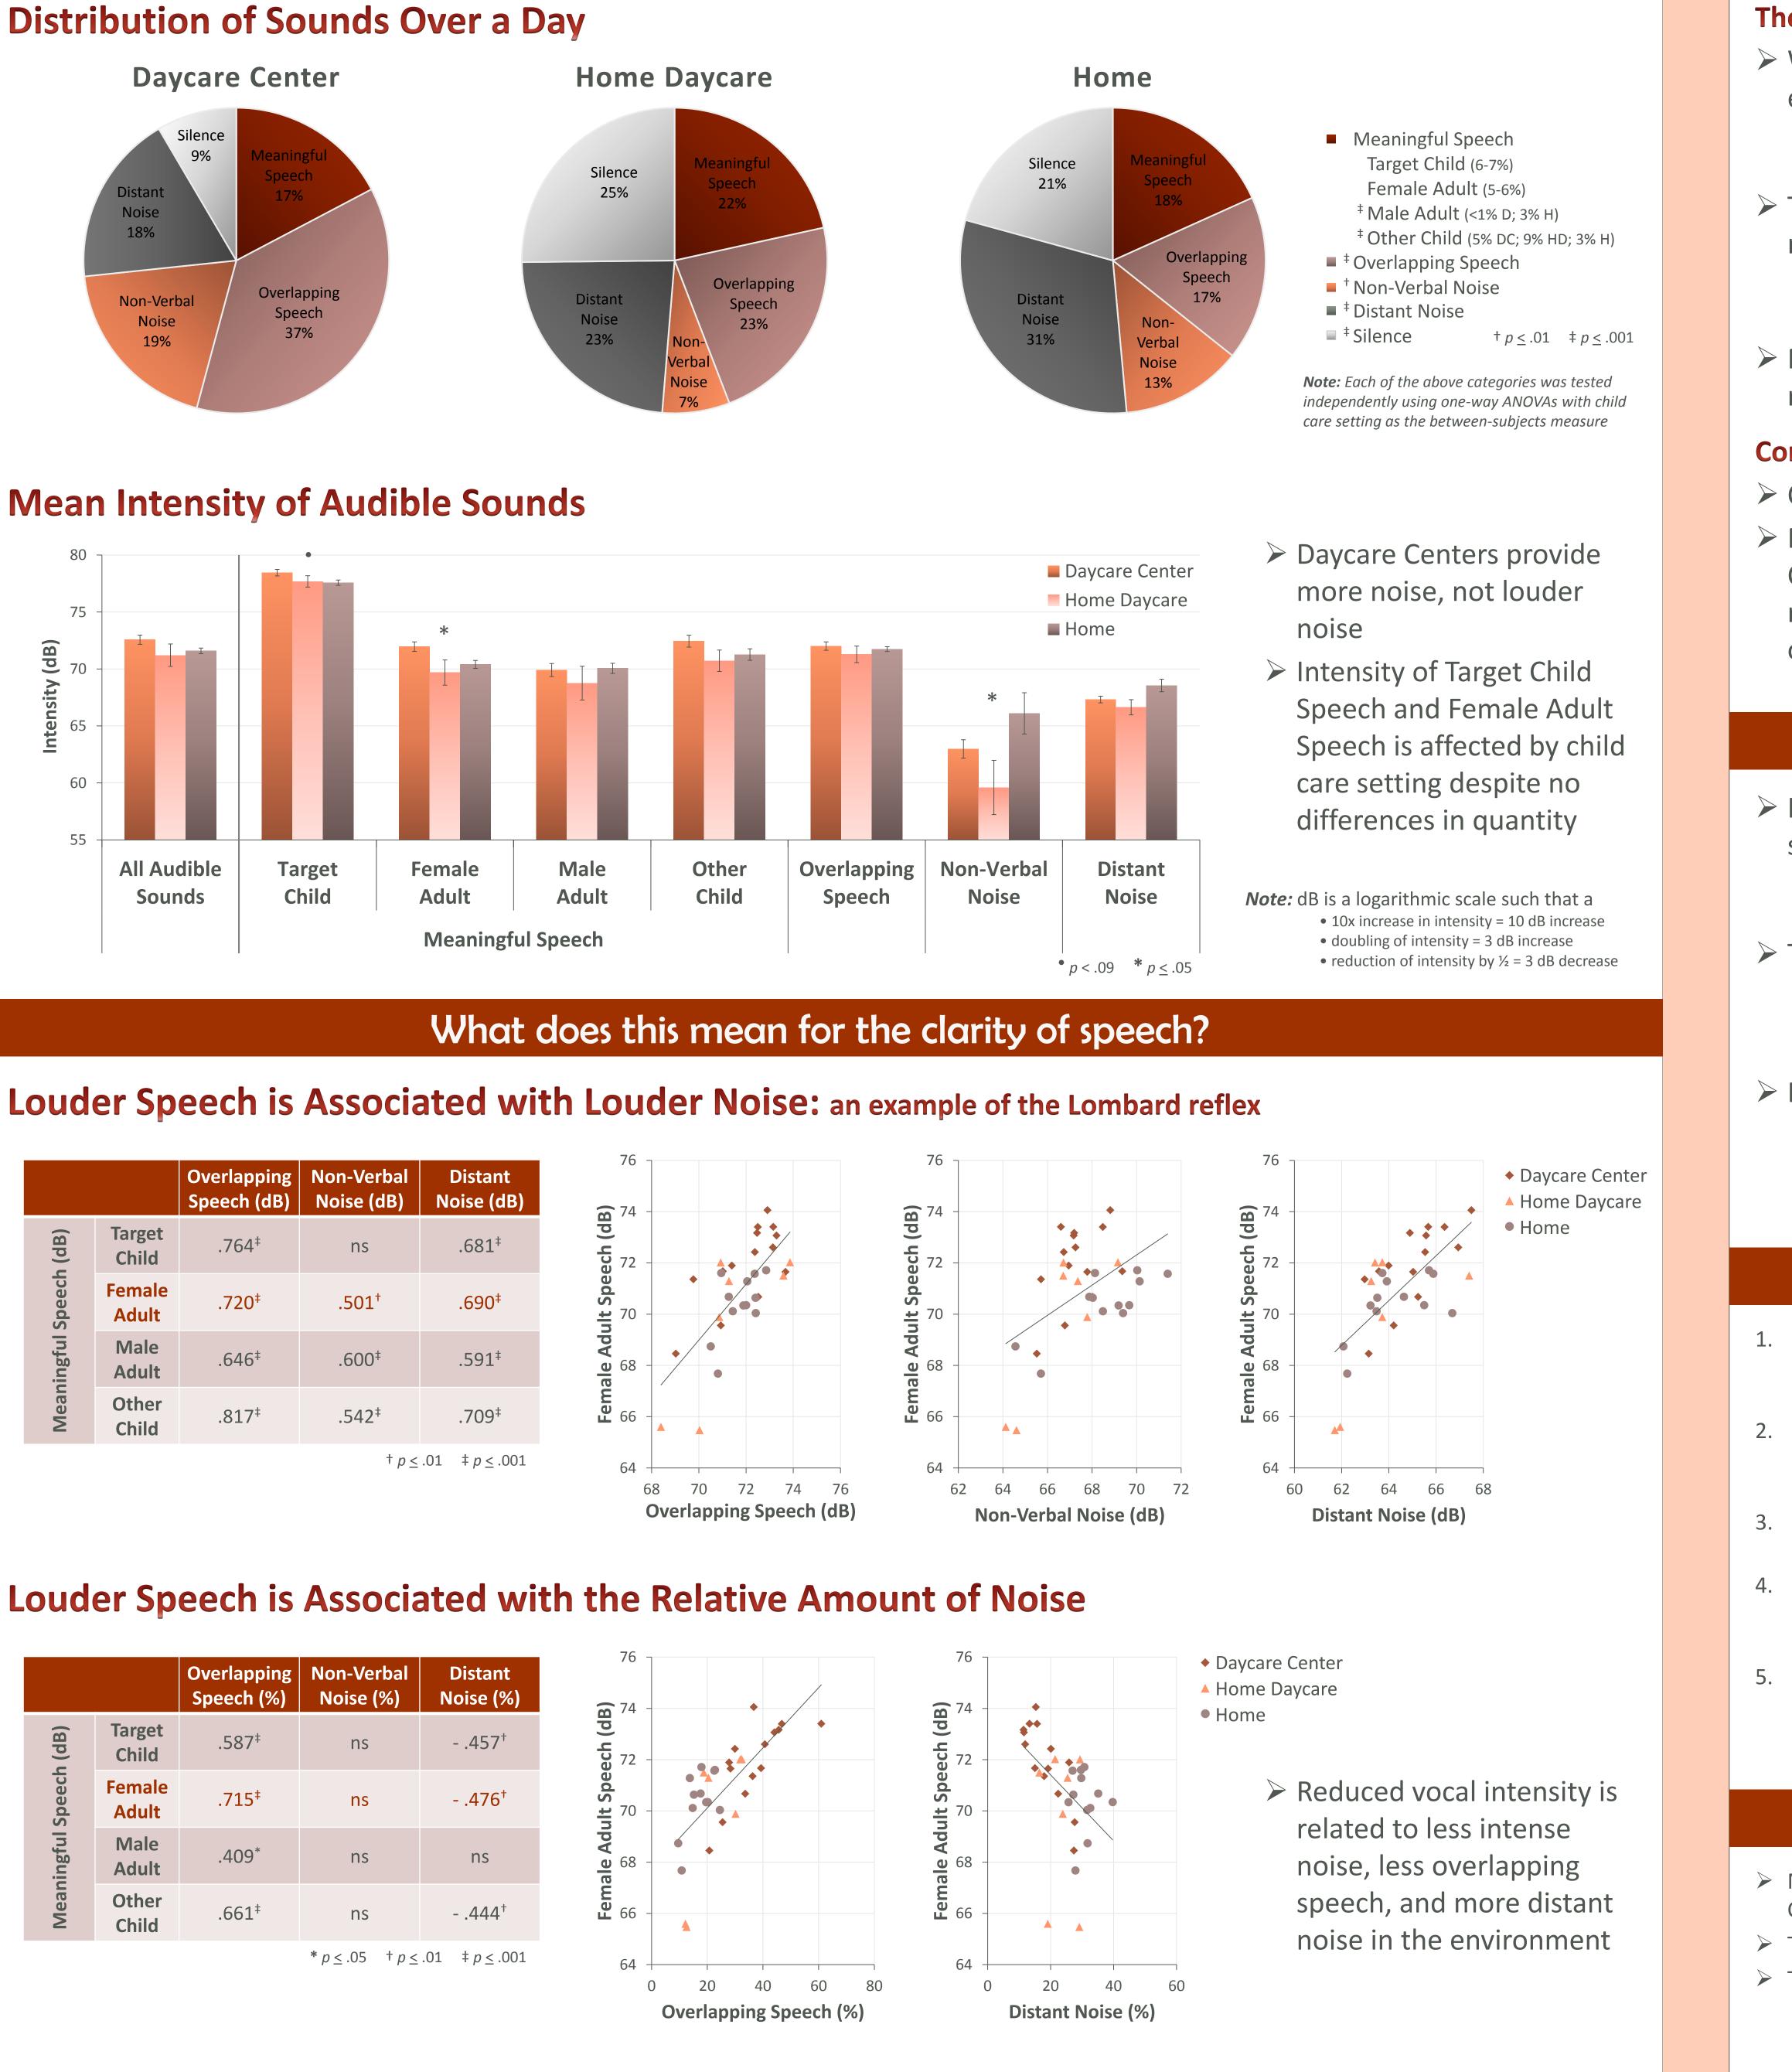

# Clarity of Language Input to Toddlers across Child Care Settings

### Discussion

### The Lombard reflex

- > We reflexively speak louder to compensate for noise in the environment
- e.g. people speak loudly when they are listening to music wearing headphones
- > The amount of overlapping speech, but not the amount of non-verbal noise affects how loud we speak
- The more we speak up, the more other people speak up as well Inanimate objects don't respond to how loud we speak
- More distant noise means less near (loud) noise and a reduced need to speak in a loud voice

### Conclusion

> Clear, effective communication occurs in all environments > For clear, effective communication to occur in a Daycare Center speech must frequently be loud to compensate for noise levels in the environment, thus providing few opportunities to communicate in a typical "indoor voice"

### **Future Directions**

- > Immediately after noise stops we continue to produce speech according to the perceived (inaccurate) noise level predict a positive relationship between the intensity of noise and the intensity of meaningful speech that follows it
- $\succ$  The type of noise affects how loud we speak
  - predict that the intensity of meaningful speech that follows overlapping speech will be louder than meaningful speech that follows non-verbal noise
- > Disentangle distant speech from distant non-verbal noise predict that the intensity of distant speech will affect the intensity of meaningful speech, whereas the intensity of distant non-verbal noise will not have an effect
